

Projet Actuariat Vie - Sujet 3

Groupe 2 DS – Amine Manai, Maha Aloui, Nassir Bouzaiene, Yasmine Attyaoui

2026-06-18

Déclaration d'utilisation de l'IA générative

Une IA générative a été utilisée pour aider à préparer la structure du fichier R Markdown, le squelette du code R et une première formulation de certaines interprétations (OpenAI ChatGPT 2026). Les calculs, les résultats, les graphiques, les choix de paramètres et la validation finale ont été vérifiés par les membres du groupe.

Introduction

On étudie une rente viagère temporaire souscrite en 2015 par des assurés anglais nés en 1955.

Au début du contrat, les assurés ont :

$$2015 - 1955 = 60 \text{ ans.}$$

Le portefeuille est composé de :

- 60% de femmes nées en 1955 ;
- 40% d'hommes nés en 1955.

Le contrat est valable entre 2015 et 2045.

On utilise les données de la Human Mortality Database (Human Mortality Database 2026) et le package **StMoMo** (Villegas, Kaishev, et Millossovich 2018), comme demandé dans le sujet.

Répartition des tâches

La répartition du travail au sein du groupe 2 DS suit l'ordre des huit questions du sujet, avec deux questions principales par membre :

- Amine Manai : questions 1 et 2, récupération des données HMD puis estimation des taux de mortalité par maximum de vraisemblance et intervalles de confiance.
- Maha Aloui : questions 3 et 4, extraction des cohortes avec **extractCohort** puis projection centrale avec le modèle de Lee-Carter et **forecast**.
- Nassir Bouzaiene : questions 5 et 6, analyse des log-taux historiques depuis 2005 puis calcul de la valeur actuelle probable selon le genre.
- Yasmine Attyaoui : questions 7 et 8, tarification unisexe avec la série **total** puis méthode unisexe adaptée au portefeuille 60/40 et interprétation du transfert de risque.

Chaque membre a aussi participé à la vérification finale du rapport, des graphiques et de la présentation.

Packages

```
install.packages(c("demography", "StMoMo"))

set.seed(42)

library(demography)
library(StMoMo)
```

Paramètres

```
cohorte <- 1955
debut <- 2015
fin <- 2045

age_debut <- debut - cohorte
ages_contrat <- age_debut:(fin - cohorte)
annees_contrat <- cohorte + ages_contrat

i <- 0.02
v <- 1 / (1 + i)
montant_rente <- 1
```

On prend un montant de rente annuel égal à 1. Si le montant réel est différent, il suffit de multiplier les valeurs actuelles probables par ce montant.

1. Télécharger les données HMD

Le pays concerné est l'Angleterre et le Pays de Galles. Dans HMD, le code est **GBRTENW** (Human Mortality Database 2026).

Pour éviter d'écrire les identifiants HMD dans le fichier source, ils sont lus depuis les variables d'environnement **HMD_USERNAME** et **HMD_PASSWORD**.

```
print(uk)

## Mortality data for England and Wales
##   Series: female male total
##   Years: 1841 - 2022
##   Ages:  0 - 110

summary(uk)

## Mortality data for England and Wales
##   Series: female male total
##   Years: 1841 - 2022
##   Ages:  0 - 110

names(uk$rate)

## [1] "female" "male"  "total"
```

Commentaire :

Une base de mortalité contient les âges, les années, les expositions et les taux observés. Ici, l'objet **HMD** donne directement les séries **female**, **male** et **total**. Cela permet de traiter séparément la mortalité des

femmes, celle des hommes et la population globale, comme demandé dans le sujet.

On transforme ensuite l'objet `demogdata` en objet utilisable avec `StMoMo`.

```
data_femme <- StMoMoData(uk, series = "female")
data_homme <- StMoMoData(uk, series = "male")
data_total <- StMoMoData(uk, series = "total")
```

```
summary(data_femme)
```

```
## Mortality data for England and Wales
##   Series:  female
##   Years: 1841 - 2022
##   Ages:   0 - 110
##   Exposure: central
```

```
summary(data_homme)
```

```
## Mortality data for England and Wales
##   Series:  male
##   Years: 1841 - 2022
##   Ages:   0 - 110
##   Exposure: central
```

```
summary(data_total)
```

```
## Mortality data for England and Wales
##   Series:  total
##   Years: 1841 - 2022
##   Ages:   0 - 110
##   Exposure: central
```

2. Estimation des taux par maximum de vraisemblance

Pour un âge x et une année t , on note :

- $D_{x,t}$: le nombre de décès ;
- $E_{x,t}$: l'exposition au risque ;
- $\mu_{x,t}$: le taux de mortalité.

Sous l'hypothèse :

$$D_{x,t} \sim \mathcal{P}(E_{x,t}\mu_{x,t}),$$

l'estimateur du maximum de vraisemblance est :

$$\hat{\mu}_{x,t} = \frac{D_{x,t}}{E_{x,t}}.$$

```
estime_mortalite <- function(data, cohorte, ages) {
  res <- data.frame()

  for (age in ages) {
    annee <- cohorte + age

    if (age %in% data$ages && annee %in% data$years) {
```

```

D <- data$Dxt[as.character(age), as.character(annee)]
E <- data$Ext[as.character(age), as.character(annee)]
mx <- D / E

bas <- exp(log(mx) - 1.96 / sqrt(pmax(D, 1)))
haut <- exp(log(mx) + 1.96 / sqrt(pmax(D, 1)))

res <- rbind(
  res,
  data.frame(
    age = age,
    annee = annee,
    D = D,
    E = E,
    mx = mx,
    bas = bas,
    haut = haut
  )
)
}
res
}

```

Les données observées vont jusqu'à 2022. Les intervalles de confiance de cette question sont donc tracés sur la partie observée de la cohorte.

```

tab_femme <- estime_mortalite(data_femme, cohorte, ages_contrat)
tab_homme <- estime_mortalite(data_homme, cohorte, ages_contrat)

```

```

tab_femme$sexe <- "Femmes"
tab_homme$sexe <- "Hommes"

```

```
head(tab_femme)
```

##	age	annee	D	E	mx	bas	haut	sexe
## 1	60	2015	1692.972	319007.3	0.005307	0.005060125	0.005565920	Femmes

```
ylim_mx <- range(c(tab_femme$bas, tab_femme$haut, tab_homme$bas, tab_homme$haut), na.rm = TRUE)
```

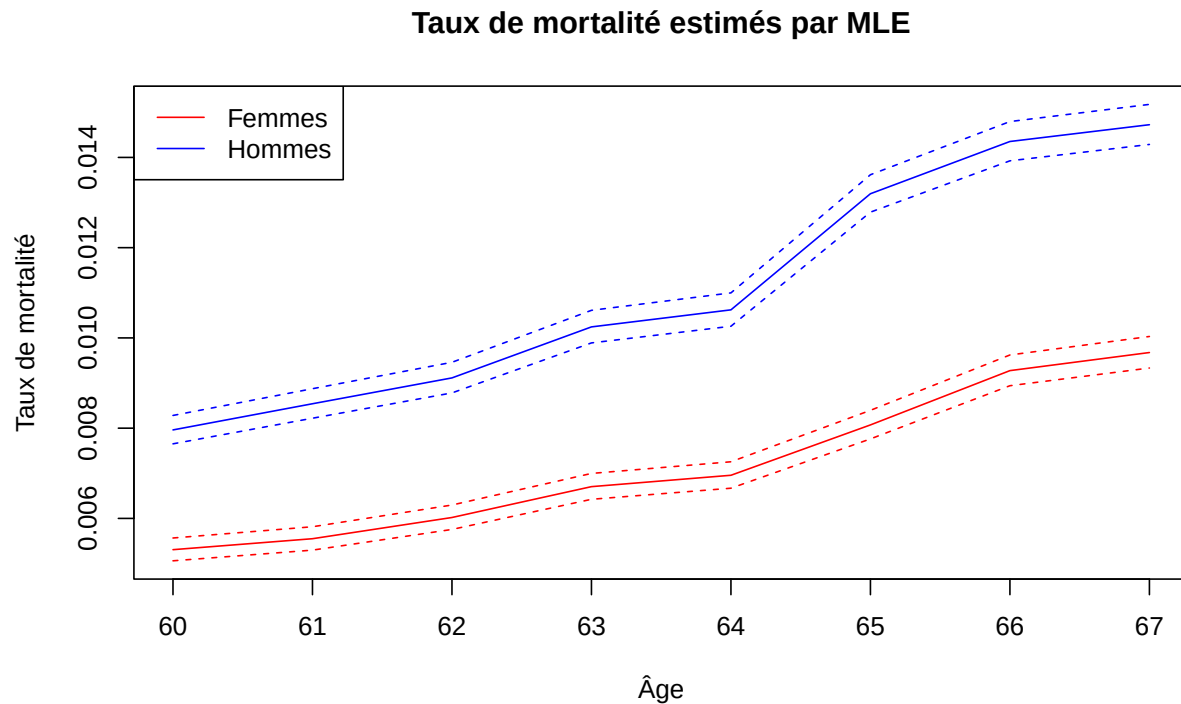

```

plot(tab_femme$age, tab_femme$mx, type = "l", col = "red",
     ylim = ylim_mx,
     xlab = "Âge", ylab = "Taux de mortalité",
     main = "Taux de mortalité estimés par MLE")
lines(tab_femme$age, tab_femme$bas, col = "red", lty = 2)
lines(tab_femme$age, tab_femme$haut, col = "red", lty = 2)

lines(tab_homme$age, tab_homme$mx, col = "blue")
lines(tab_homme$age, tab_homme$bas, col = "blue", lty = 2)
lines(tab_homme$age, tab_homme$haut, col = "blue", lty = 2)

legend("topleft", c("Femmes", "Hommes"), col = c("red", "blue"), lty = 1)

```

Commentaire :

On vérifie que l'estimation utilisée correspond à la procédure du cours :

$$\hat{\mu}_{x,t} = \frac{D_{x,t}}{E_{x,t}}.$$

Les taux masculins sont généralement au-dessus des taux féminins. Cela traduit une mortalité masculine plus élevée aux âges considérés. Les intervalles de confiance mesurent l'incertitude statistique liée au nombre de décès observés et aux expositions.

3. Log-taux historiques avec `extractCohort`

On utilise maintenant la fonction `extractCohort`, comme demandé dans le sujet.

```

taux_femme_hist <- data_femme$Dxt / data_femme$Ext
taux_homme_hist <- data_homme$Dxt / data_homme$Ext

coh_femme_hist <- extractCohort(taux_femme_hist, cohort = cohorte)
coh_homme_hist <- extractCohort(taux_homme_hist, cohort = cohorte)

ages_hist_femme <- as.numeric(names(coh_femme_hist))
ages_hist_homme <- as.numeric(names(coh_homme_hist))

```

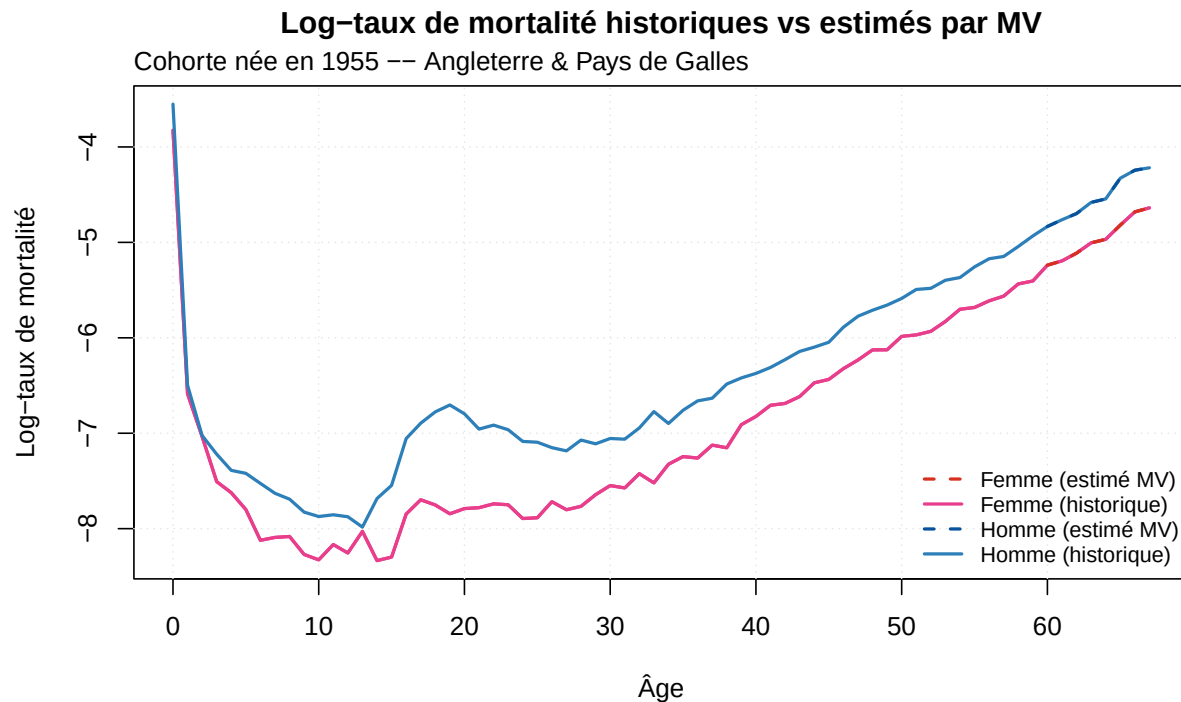

Le graphique suivant réunit les log-taux historiques extraits par cohorte et les log-taux estimés par maximum de vraisemblance sur la période du contrat.

```

ylim_comp <- range(
  log(tab_femme$mx),
  log(tab_homme$mx),
  log(coh_femme_hist),
  log(coh_homme_hist),
  na.rm = TRUE
)

plot(ages_hist_femme, log(coh_femme_hist), type = "l",
     col = "#e83e8c", lwd = 2,
     ylim = ylim_comp,
     xlab = "Âge", ylab = "Log-taux de mortalité",
     main = "Log-taux de mortalité historiques vs estimés par MV")
mtext("Cohorte née en 1955 -- Angleterre & Pays de Galles",
     side = 3, line = 0.3, adj = 0)
grid(col = "gray90")
lines(ages_hist_femme, log(coh_femme_hist), col = "#e83e8c", lwd = 2)
lines(ages_hist_homme, log(coh_homme_hist), col = "#2c7fb8", lwd = 2)
lines(tab_femme$age, log(tab_femme$mx), col = "#d7301f", lwd = 2, lty = 2)
lines(tab_homme$age, log(tab_homme$mx), col = "#08519c", lwd = 2, lty = 2)
legend("bottomright",
     c("Femme (estimé MV)", "Femme (historique)",
       "Homme (estimé MV)", "Homme (historique)"),
     col = c("#d7301f", "#e83e8c", "#08519c", "#2c7fb8"),
     lty = c(2, 1, 2, 1),
     lwd = 2,
     bty = "n",
     cex = 0.8)

```

Commentaire :

La fonction `extractCohort` réalise une lecture longitudinale : elle suit une même génération au cours du temps. Cette lecture est adaptée à une rente, car le contrat concerne des assurés nés la même année.

Sur les années observées, les log-taux historiques et les log-taux estimés par maximum de vraisemblance coïncident, car l'estimateur utilisé est $D_{x,t}/E_{x,t}$. Le graphique confirme donc la cohérence entre l'extraction de cohorte et l'estimation directe.

4. Projection centrale sur 25 ans avec forecast

On ajuste un modèle de Lee-Carter (Lee et Carter 1992) avec `StMoMo` (Villegas, Kaishev, et Millosovich 2018).

```
modele_lc <- lc(link = "log")

ages_fit <- 50:100
years_fit <- 1960:max(data_femme$years)

fit_femme <- fit(modele_lc, data = data_femme, ages.fit = ages_fit, years.fit = years_fit)

## StMoMo: Start fitting with gnm
## Initialising
## Running start-up iterations..
## Running main iterations.....
## Done
## StMoMo: Finish fitting with gnm

fit_homme <- fit(modele_lc, data = data_homme, ages.fit = ages_fit, years.fit = years_fit)

## StMoMo: Start fitting with gnm
```

```

## Initialising
## Running start-up iterations..
## Running main iterations.....
## Done
## StMoMo: Finish fitting with gnm

fit_total <- fit(modele_lc, data = data_total, ages.fit = ages_fit, years.fit = years_fit)

## StMoMo: Start fitting with gnm
## Initialising
## Running start-up iterations..
## Running main iterations.....
## Done
## StMoMo: Finish fitting with gnm

prev_femme_25 <- forecast(fit_femme, h = 25)
prev_homme_25 <- forecast(fit_homme, h = 25)
prev_total_25 <- forecast(fit_total, h = 25)

```

Projection centrale de l'indice temporel k_t pour les femmes et les hommes :

```

plot_kt_projection <- function(prev, titre, couleur) {
  fit <- prev$model
  annees_hist <- fit$years
  annees_prev <- prev$kt.f$years
  kt_hist <- as.numeric(fit$kt[1, ])
  kt_prev <- prev$kt.f

  moyenne <- as.numeric(kt_prev$mean[1, ])
  niveaux <- kt_prev$level
  niveau_large <- which.max(niveaux)
  niveau_central <- which.min(niveaux)

  bas_large <- as.numeric(kt_prev$lower[1, , niveau_large])
  haut_large <- as.numeric(kt_prev$upper[1, , niveau_large])
  bas_central <- as.numeric(kt_prev$lower[1, , niveau_central])
  haut_central <- as.numeric(kt_prev$upper[1, , niveau_central])

  limites_y <- range(
    kt_hist,
    moyenne,
    bas_large,
    haut_large,
    na.rm = TRUE
  )

  plot(annees_hist, kt_hist, type = "l",
       xlim = c(2000, tail(annees_prev, 1)),
       ylim = limites_y,
       xlab = "Année", ylab = "Indice k_t",
       main = titre,
       lwd = 2.2,
       col = couleur,
       bty = "n",
       las = 1)
  grid(col = "gray92")
}

```

```

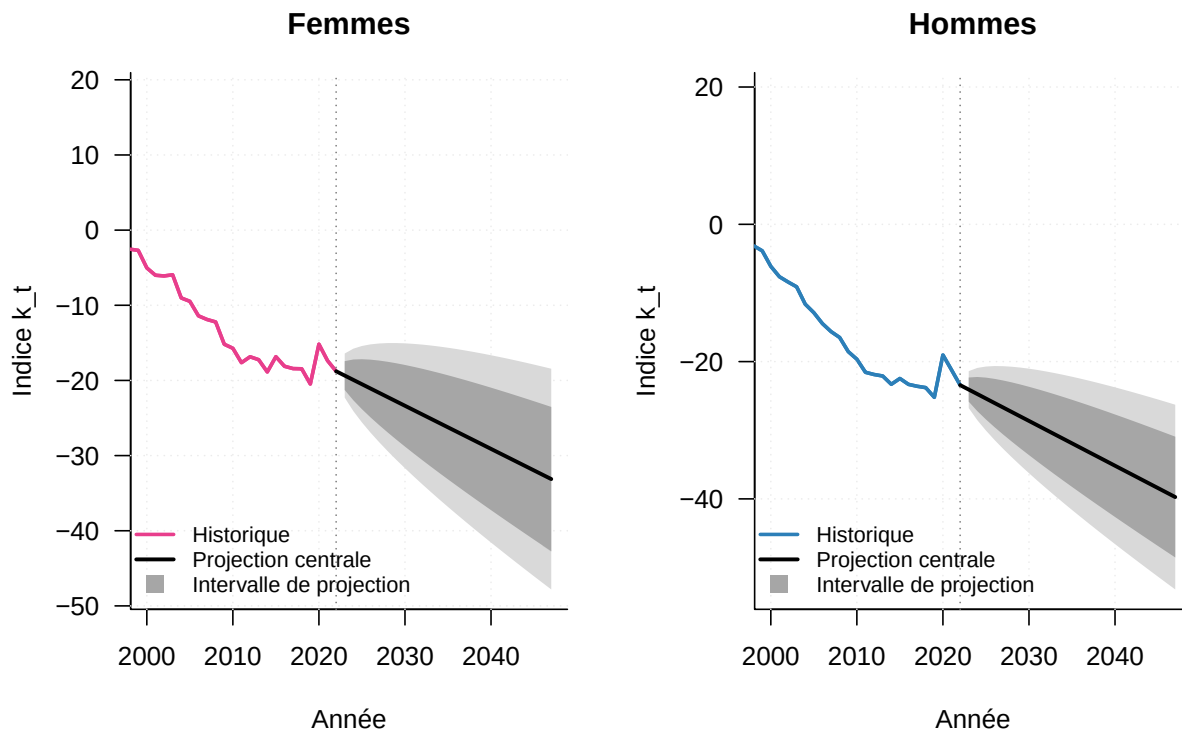

polygon(c(annees_prev, rev(annees_prev)),
       c(bas_large, rev(haut_large)),
       col = "gray85", border = NA)
polygon(c(annees_prev, rev(annees_prev)),
       c(bas_central, rev(haut_central)),
       col = "gray65", border = NA)

lines(annees_hist, kt_hist, lwd = 2.2, col = couleur)
lines(c(annees_prev[1] - 1, anneer_prev),
      c(tail(kt_hist, 1), moyenne),
      lwd = 2.4, col = "black")
abline(v = anneer_prev[1] - 1, lty = 3, col = "gray45")

legend("bottomleft",
      c("Historique", "Projection centrale", "Intervalle de projection"),
      col = c(couleur, "black", "gray65"),
      lty = c(1, 1, NA),
      lwd = c(2.2, 2.4, NA),
      pch = c(NA, NA, 15),
      pt.cex = 1.5,
      bty = "n",
      cex = 0.8)
}

par(mfrow = c(1, 2), mar = c(4.6, 4.7, 3.2, 1.3))
plot_kt_projection(prev_femme_25, "Femmes", "#e83e8c")
plot_kt_projection(prev_homme_25, "Hommes", "#2c7fb8")

```

```
par(mfrow = c(1, 1))
```

Commentaire :

Dans le modèle de Lee-Carter, les composantes s'interprètent ainsi :

- a_x représente le profil moyen de mortalité selon l'âge ;
- b_x mesure la sensibilité de chaque âge à l'évolution temporelle ;
- k_t représente le niveau global de mortalité au cours du temps.

La projection centrale correspond à la moyenne prévue par `forecast`. Ce n'est ni une borne haute ni une borne basse : c'est la trajectoire centrale de k_t , à partir de laquelle on déduit les taux futurs. Lorsque k_t diminue, cela traduit une amélioration attendue de la mortalité si la tendance passée se prolonge.

5. Log-taux historiques depuis 2005

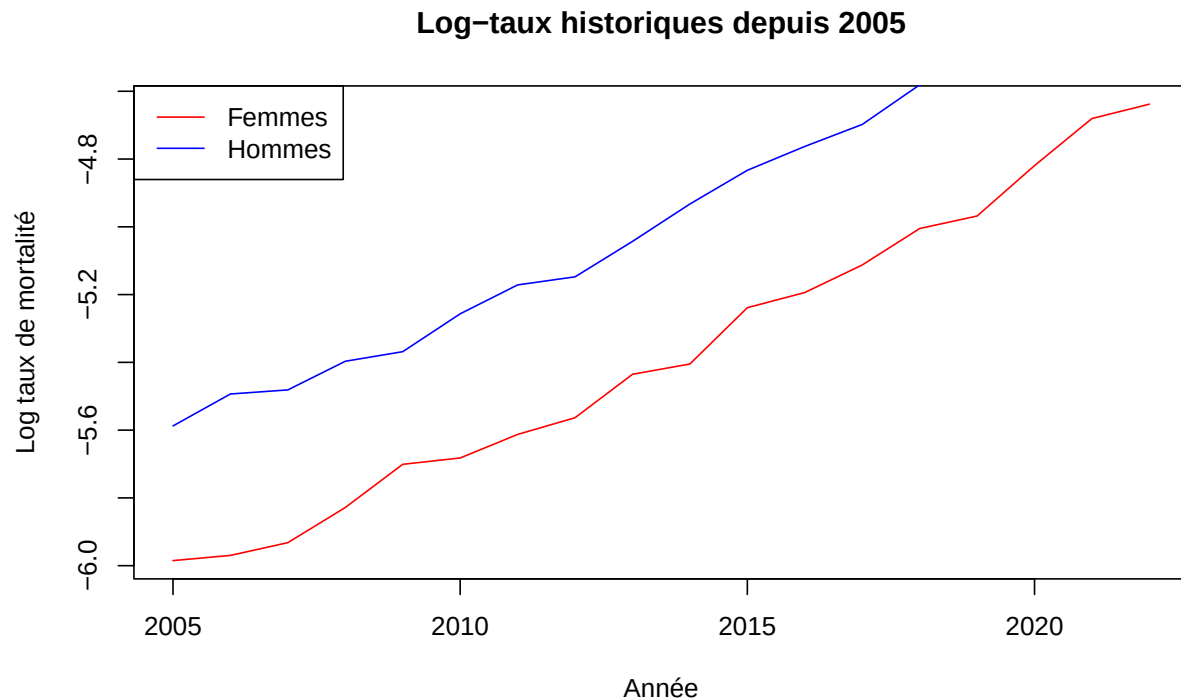

```
age_2005 <- 2005 - cohorte
ages_depuis_2005 <- age_2005:max(data_femme$ages)

log_femme_2005 <- coh_femme_hist[as.character(ages_depuis_2005)]
log_homme_2005 <- coh_homme_hist[as.character(ages_depuis_2005)]

annees_depuis_2005 <- cohorte + ages_depuis_2005

ok_2005 <- !is.na(log_femme_2005) & !is.na(log_homme_2005)

plot(annees_depuis_2005[ok_2005], log(log_femme_2005[ok_2005]),
     type = "l", col = "red",
     xlab = "Année", ylab = "Log taux de mortalité",
     main = "Log-taux historiques depuis 2005")
lines(annees_depuis_2005[ok_2005], log(log_homme_2005[ok_2005]), col = "blue")
legend("topleft", c("Femmes", "Hommes"), col = c("red", "blue"), lty = 1)
```

Commentaire :

À partir de 2005, la cohorte née en 1955 a 50 ans. On observe donc sa trajectoire avant l'entrée dans le contrat en 2015. Les log-taux augmentent avec l'âge, ce qui correspond au fait que la mortalité croît aux âges adultes et élevés. Les hommes conservent en général des log-taux supérieurs à ceux des femmes.

6. Valeur actuelle probable du contrat selon le genre

Pour une rente temporaire à termes anticipés :

$$VAP = \sum_{k=0}^{n-1} v^k {}_k p_x.$$

```
rente_temporaire <- function(qx, v) {
  n <- length(qx)
  survie <- c(1, cumprod(1 - qx[-n]))
  sum(v^(0:(n - 1)) * survie)
}
```

On prépare une matrice de taux contenant les taux ajustés observés et les taux projetés.

```
matrice_complete <- function(fit, prev) {
  cbind(fitted(fit, type = "rates"), prev$rates)
}
```

Le contrat va jusqu'en 2045. Comme les données observées s'arrêtent en 2022, on projette jusqu'en 2045.

```
h_prix <- fin - max(data_femme$years)
prev_femme_prix <- forecast(fit_femme, h = h_prix)
```

```

prev_homme_prix <- forecast(fit_homme, h = h_prix)
prev_total_prix <- forecast(fit_total, h = h_prix)

mat_femme <- matrice_complete(fit_femme, prev_femme_prix)
mat_homme <- matrice_complete(fit_homme, prev_homme_prix)
mat_total <- matrice_complete(fit_total, prev_total_prix)

```

On transforme les taux centraux μ_x en probabilités annuelles q_x avec l'approximation :

$$q_x = 1 - \exp(-\mu_x).$$

```

qx_contrat <- function(mat, cohorte, ages) {
  qx <- rep(NA, length(ages))

  for (j in 1:length(ages)) {
    age <- ages[j]
    annee <- cohorte + age
    mx <- mat[as.character(age), as.character(annee)]
    qx[j] <- 1 - exp(-mx)
  }

  qx
}

qx_femme <- qx_contrat(mat_femme, cohorte, ages_contrat)
qx_homme <- qx_contrat(mat_homme, cohorte, ages_contrat)

vap_femme <- montant_rente * rente_temporaire(qx_femme, v)
vap_homme <- montant_rente * rente_temporaire(qx_homme, v)

resultat_genre <- data.frame(
  sexe = c("Femmes", "Hommes"),
  VAP = c(vap_femme, vap_homme)
)

resultat_genre

##      sexe      VAP
## 1 Femmes 19.49538
## 2 Hommes 18.16818

```

Commentaire :

La valeur actuelle probable est déterminée par équivalence actuarielle entre les paiements futurs de rente et leur probabilité de versement. On observe que la VAP féminine est plus élevée. Cela s'explique par une mortalité plus faible des femmes : l'assureur s'attend donc à verser la rente plus longtemps en moyenne.

7. Approfondissement 1 – Sensibilité de la VAP au taux d'actualisation

7.1 Motivation et cadre théorique

La valeur actuelle probable dépend de deux sources principales : la survie future et l'actualisation financière. À mortalité donnée, une hausse du taux d'actualisation diminue la valeur des paiements futurs, surtout ceux

qui arrivent tard dans le contrat.

Pour une rente temporaire à termes anticipés de montant R , on utilise :

$$VAP(i) = R \sum_{k=0}^{n-1} \frac{{}_k p_x}{(1+i)^k}.$$

Le taux de référence du rapport est $i = 2\%$. On compare donc plusieurs taux autour de ce niveau.

```
qx_total <- qx_contrat(mat_total, cohorte, ages_contrat)

vap_total <- montant_rente * rente_temporaire(qx_total, v)
vap_unisexe_portefeuille <- 0.60 * vap_femme + 0.40 * vap_homme

resultats_reference <- data.frame(
  methode = c(
    "Femmes",
    "Hommes",
    "Unisexe série Total HMD",
    "Unisexe portefeuille 60% femmes / 40% hommes"
  ),
  VAP = c(
    vap_femme,
    vap_homme,
    vap_total,
    vap_unisexe_portefeuille
  )
)

resultats_reference
```

##		methode	VAP
## 1		Femmes	19.49538
## 2		Hommes	18.16818
## 3		Unisexe série Total HMD	18.81099
## 4	Unisexe portefeuille 60% femmes / 40% hommes		18.96450

7.2 Calcul des VAP pour chaque taux

```
taux_actualisation <- c(0.00, 0.01, 0.02, 0.03, 0.04, 0.05)

vap_pour_taux <- function(qx, taux, montant = 1) {
  montant * rente_temporaire(qx, 1 / (1 + taux))
}

table_sensibilite <- data.frame()

for (taux in taux_actualisation) {
  vap_f <- vap_pour_taux(qx_femme, taux, montant_rente)
  vap_h <- vap_pour_taux(qx_homme, taux, montant_rente)
  vap_t <- vap_pour_taux(qx_total, taux, montant_rente)
  vap_p <- 0.60 * vap_f + 0.40 * vap_h

  table_sensibilite <- rbind(
```

```

table_sensibilite,
data.frame(
  taux = taux,
  Femmes = vap_f,
  Hommes = vap_h,
  Total_HMD = vap_t,
  Portefeuille_60_40 = vap_p
)
)
}

```

```
table_sensibilite
```

```

##   taux   Femmes   Hommes Total_HMD Portefeuille_60_40
## 1 0.00 24.95350 22.95334  23.92140          24.15344
## 2 0.01 21.96654 20.34252  21.12879          21.31693
## 3 0.02 19.49538 18.16818  18.81099          18.96450
## 4 0.03 17.43646 16.34477  16.87374          16.99978
## 5 0.04 15.70904 14.80524  15.24338          15.34752
## 6 0.05 14.24986 13.49676  13.86204          13.94862

```

7.3 Variation relative par rapport au taux de référence

```

ligne_reference <- table_sensibilite[table_sensibilite$taux == i, ]

variation_sensibilite <- table_sensibilite
variation_sensibilite[, -1] <- 100 * sweep(
  table_sensibilite[, -1],

```

Sensibilité de la VAP au taux d'actualisation

Commentaire :

La VAP décroît quand le taux d'actualisation augmente. L'effet est mécanique : les paiements éloignés reçoivent un poids plus faible. La sensibilité est plus forte pour les groupes à plus longue durée de paiement attendue, donc en général pour les femmes. Pour un produit de rente, le risque financier de taux ne peut donc pas être séparé du risque de longévité.

8. Approfondissement 2 – Comparaison de modèles de mortalité StMoMo

8.1 Motivation et présentation des modèles

Le modèle de Lee-Carter est une référence, mais il n'est pas le seul modèle disponible dans **StMoMo**. Pour tester la robustesse des conclusions, on compare trois modèles :

- **Lee-Carter (LC)** : modèle simple avec un seul facteur temporel k_t , adapté à une première projection

globale.

- **Age-Period-Cohort (APC)** : ajoute un effet de cohorte, utile lorsque certaines générations ont une mortalité durablement différente (Renshaw et Haberman 2006).
- **Cairns-Blake-Dowd (CBD)** : modèle orienté vers les âges adultes et élevés, souvent utilisé pour les risques de longévité et les portefeuilles de rentes (Cairns, Blake, et Dowd 2006).

Le benchmark utilise la série `total` afin de comparer les modèles sur une même base. On ajuste chaque modèle sur 1960-2015, puis on teste sa projection sur 2016-2022, période observée dans HMD. Le critère principal retenu est la RMSE des log-taux projetés.

## StMoMo: Finish fitting with gnm
if (!is.null(fit_total_apc)) {
  plot(fit_total_apc)
}

```

Commentaire :

Le modèle APC sépare trois effets : l'âge, la période et la cohorte. Il devient intéressant lorsque la génération de naissance apporte une information supplémentaire. Dans notre sujet, la cohorte 1955 est centrale ; l'APC est donc pertinent pour vérifier si un effet générationnel modifie la projection de mortalité et la VAP.

8.3 Ajustement du modèle CBD

```
fit_total_cbd <- ajuster_stmomo(
  modeles_stmomo[["CBD"]],
  data_total,
  ages_fit_benchmark,
  1960:max(data_total$years),
  "CBD"
)

## StMoMo: Finish fitting with gnm
if (!is.null(fit_total_cbd)) {
  plot(fit_total_cbd)
}
```

Commentaire :

Le modèle CBD est adapté aux âges adultes et élevés, ce qui correspond au périmètre du contrat : les assurés passent de 60 à 90 ans. Il est moins général que Lee-Carter, mais il peut être plus ciblé pour un portefeuille de rentes où la longévité aux âges élevés est le risque principal.

8.4 Tableau comparatif des trois modèles

```
vap_modele_total <- function(fit_modele, nom) {
  prev <- prevoir_stmomo(fit_modele, h_prix, nom)

  if (is.null(fit_modele) || is.null(prev)) {
    return(NA_real_)
  }

  mat <- matrice_complete(fit_modele, prev)
  qx <- qx_contrat(mat, cohorte, ages_contrat)
  montant_rente <- rente_temporaire(qx, v)
}

fits_total_modeles <- list(
  "Lee-Carter" = fit_total,
```

```

"APC" = fit_total_apc,
"CBD" = fit_total_cbd
)

vap_par_modele <- data.frame(
  modele = names(fits_total_modeles),
  VAP_total_HMD = sapply(names(fits_total_modeles), function(nom) {
    vap_modele_total(fits_total_modeles[[nom]], nom)
  })
)

tableau_benchmark <- merge(
  table_comparaison_modeles,
  vap_par_modele,
  by = "modele",
  all.x = TRUE
)

tableau_benchmark

```

```

##      modele  RMSE_log  MAE_log  logLik AIC_indicatif BIC_indicatif
## 1      APC 0.10167282 0.07869041 -19452.72    39403.44    40245.04
## 2      CBD 0.12155711 0.08824834 -24502.68    49381.37    50016.79

##      parametres VAP_total_HMD
## 1          249      18.91582
## 2          188      18.86714
## 3          125      18.81099

```

Commentaire de choix :

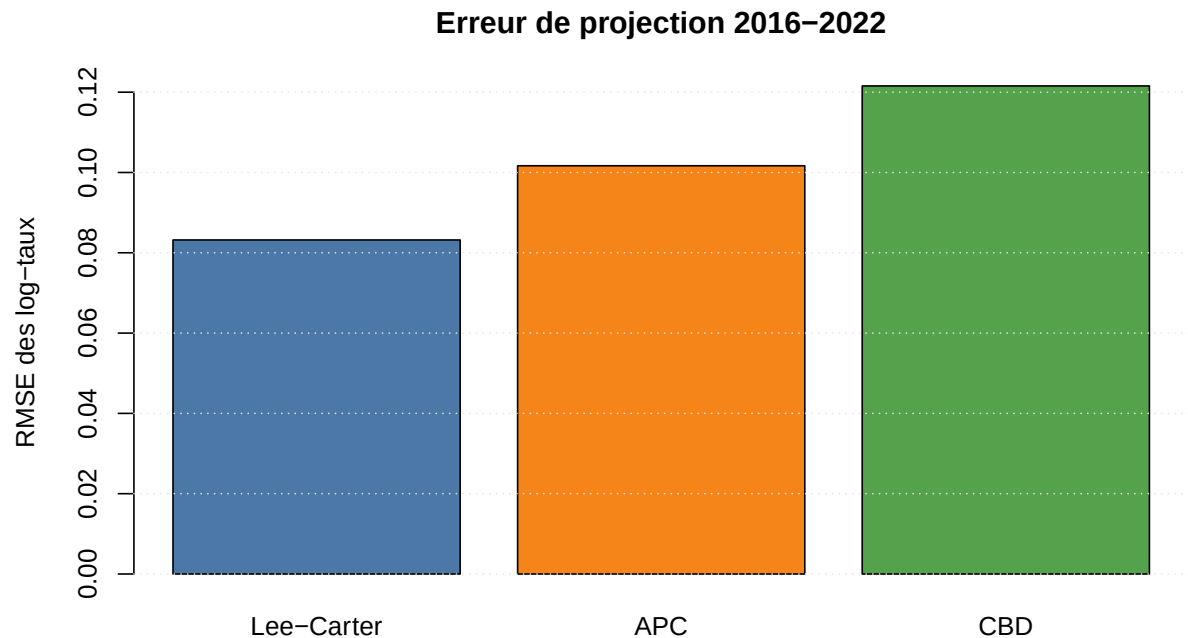

- Choisir **Lee-Carter** pour une analyse pédagogique, lisible et stable, ou lorsque l'on veut une référence simple à expliquer.
- Choisir **APC** lorsque l'effet de génération est important, par exemple si certaines cohortes ont une mortalité structurellement différente.
- Choisir **CBD** pour un portefeuille centré sur les âges élevés, notamment les rentes et le risque de longévité.
- Choisir le modèle ayant la meilleure performance de validation lorsque l'objectif principal est la qualité prédictive. Ici, ce choix est donné par la RMSE hors échantillon.

8.5 Graphique comparatif

```

if (nrow(table_modeles_valides) > 0) {
  barplot(table_modeles_valides$RMSE_log,
    names.arg = table_modeles_valides$modele,
    col = c("#4c78a8", "#f58518", "#54a24b")[seq_len(nrow(table_modeles_valides))],
    ylab = "RMSE des log-taux",
    main = "Erreur de projection 2016-2022")
  grid(nx = NA, ny = NULL, col = "gray90")
}

```

8.6 Visualisation des probabilités projetées

```
couleurs_modeles <- c("Lee-Carter" = "#4c78a8", "APC" = "#f58518", "CBD" = "#54a24b")
qx_modeles <- list()

for (nom in names(fits_total_modeles)) {
  prev <- prevoir_stmomo(fits_total_modeles[[nom]], h_prix, nom)
  if (!is.null(prev) && !is.null(fits_total_modeles[[nom]])) {
    mat <- matrice_complete(fits_total_modeles[[nom]], prev)
    qx_modeles[[nom]] <- qx_contrat(mat, cohorte, ages_contrat)
  }
}

if (length(qx_modeles) > 0) {
  ylim_qx <- range(unlist(qx_modeles), na.rm = TRUE)
  premier <- names(qx_modeles)[1]

  plot(ages_contrat, qx_modeles[[premier]],
       type = "l", lwd = 2,
       col = couleurs_modeles[premier],
       ylim = ylim_qx,
       xlab = "Âge",
       ylab = "Probabilité annuelle de décès qx",
       main = "Probabilités projetées selon le modèle")
  grid(col = "gray90")

  if (length(qx_modeles) > 1) {
    for (nom in names(qx_modeles)[-1]) {
```

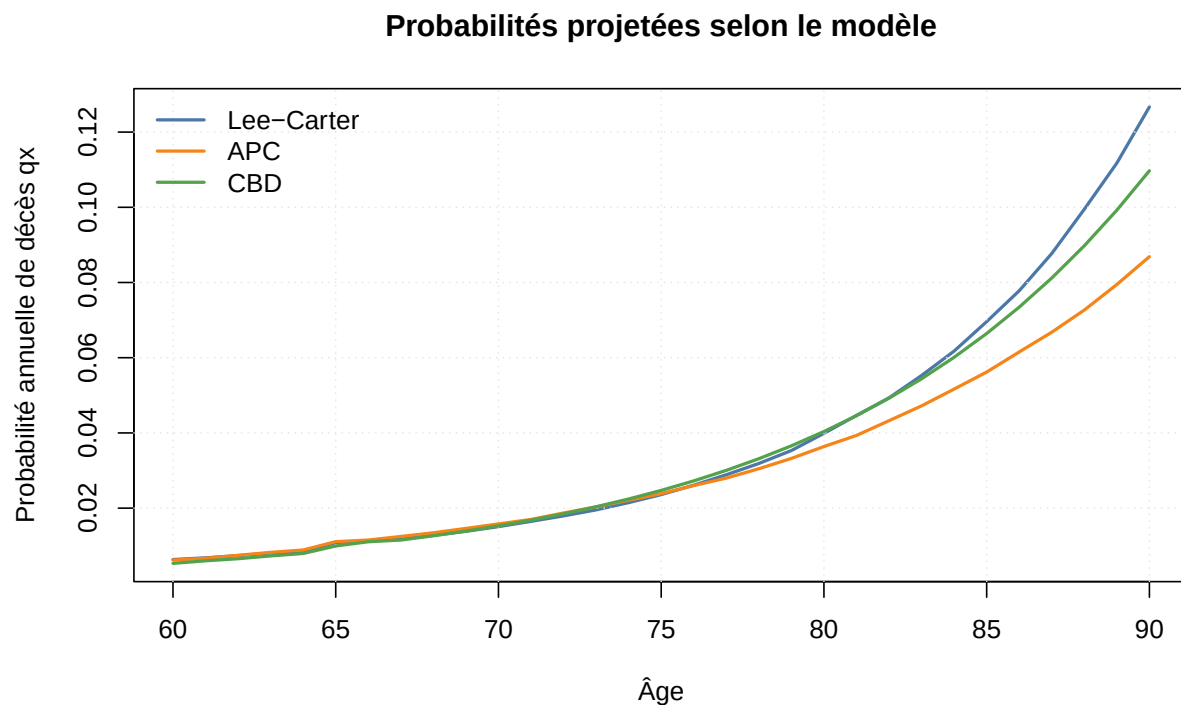

```

    lines(ages_contrat, qx_modeles[[nom]],
          lwd = 2, col = couleurs_modeles[nom])
  }
}

legend("topleft",
      names(qx_modeles),
      col = couleurs_modeles[names(qx_modeles)],
      lty = 1, lwd = 2, bty = "n")
}

```

Commentaire :

Les écarts entre courbes semblent parfois faibles en niveau annuel, mais ils peuvent produire une différence visible sur la VAP, car la rente additionne les paiements sur toute la durée du contrat. Le choix du modèle doit donc être justifié à la fois statistiquement et actuariellement.

9. Approfondissement 3 – Effet de la composition du portefeuille

9.1 Motivation et formule

Le portefeuille réel contient 60% de femmes et 40% d'hommes. Une prime unisexe fondée uniquement sur la série **total** HMD peut être éloignée de la structure propre de l'assureur si son portefeuille n'a pas la même composition que la population nationale.

Pour une proportion p de femmes, la VAP moyenne du portefeuille est :

$$VAP(p) = p \times VAP_F + (1 - p) \times VAP_H.$$

9.2 Calcul sur la grille de proportions

```
proportions_femmes <- seq(0, 1, by = 0.05)

table_composition <- data.frame(
  proportion_femmes = proportions_femmes,
  proportion_hommes = 1 - proportions_femmes,
  VAP_portefeuille = proportions_femmes * vap_femme +
    (1 - proportions_femmes) * vap_homme,
  ecart_vs_total_HMD = proportions_femmes * vap_femme +
    (1 - proportions_femmes) * vap_homme -
    vap_total
)

table_composition
```

9.3 Proportion équivalente à la série Total HMD

```
proportion_equivalente_total <- (vap_total - vap_homme) / (vap_femme - vap_homme)

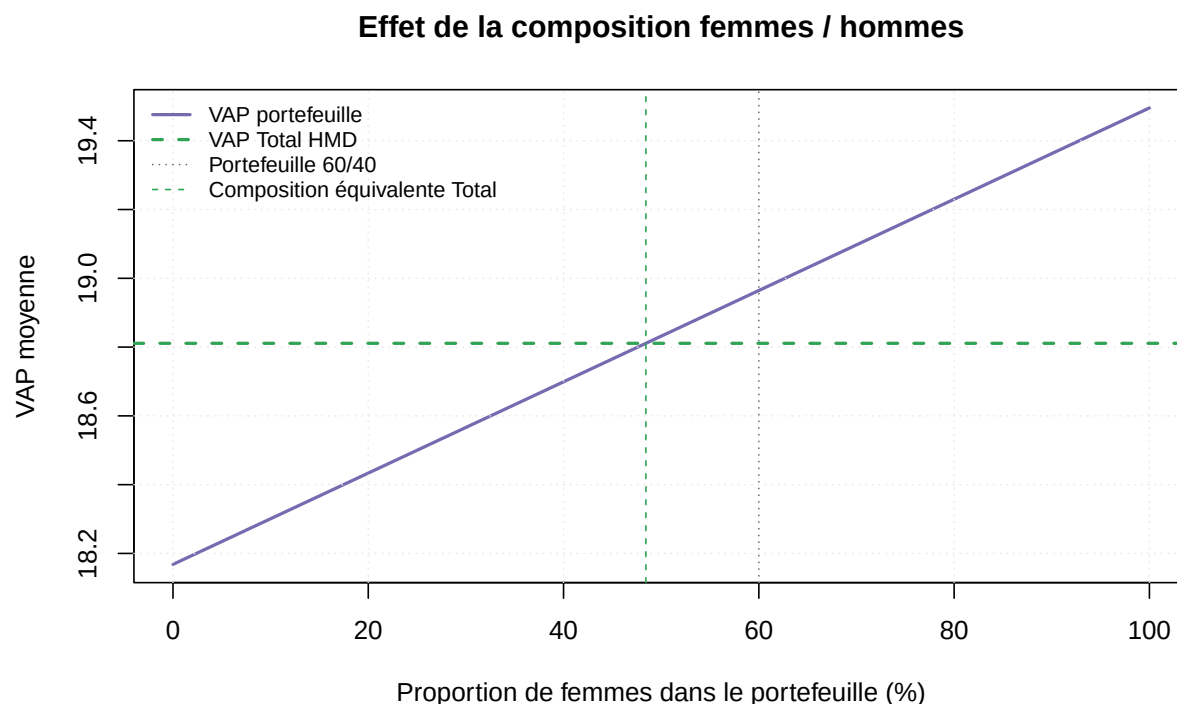

data.frame(
  proportion_femmes_equivalente = proportion_equivalente_total,
  proportion_hommes_equivalente = 1 - proportion_equivalente_total
)

##   proportion_femmes_equivalente proportion_hommes_equivalente
## 1                0.4843361                0.5156639
```

Cette proportion est celle qui rend la moyenne pondérée femmes/hommes égale à la VAP obtenue avec la série total HMD.

9.4 Graphique

```
plot(table_composition$proportion_femmes * 100,
     table_composition$VAP_portefeuille,
     type = "l", lwd = 2, col = "#756bb1",
     xlab = "Proportion de femmes dans le portefeuille (%)",
     ylab = "VAP moyenne",
     main = "Effet de la composition femmes / hommes")
grid(col = "gray90")
abline(h = vap_total, lty = 2, col = "#31a354", lwd = 2)
abline(v = 60, lty = 3, col = "gray40")
abline(v = proportion_equivalente_total * 100, lty = 2, col = "#31a354")
legend("topleft",
      c("VAP portefeuille", "VAP Total HMD", "Portefeuille 60/40", "Composition équivalente Total"),
      col = c("#756bb1", "#31a354", "gray40", "#31a354"),
      lty = c(1, 2, 3, 2),
      lwd = c(2, 2, 1, 1),
      bty = "n", cex = 0.8)
```

9.5 Analyse du transfert de risque selon la composition

```
prime_unisexe_60_40 <- 0.60 * vap_femme + 0.40 * vap_homme

transfert_60_40 <- data.frame(
  groupe = c("Femmes", "Hommes"),
  cout_actuariel = c(vap_femme, vap_homme),
  prime_unisexe_portefeuille = c(prime_unisexe_60_40, prime_unisexe_60_40),
  difference_prime_moins_cout = c(
```

```

    prime_unisexe_60_40 - vap_femme,
    prime_unisexe_60_40 - vap_homme
  )
)

transfert_60_40

##   groupe cout_actuariel prime_unisexe_portefeuille difference_prime_moins_cout
## 1 Femmes      19.49538      18.9645      -0.5308793
## 2 Hommes      18.16818      18.9645       0.7963189

```

Commentaire :

Quand la proportion de femmes augmente, la VAP moyenne augmente, car la longévité attendue du portefeuille augmente. Une prime unisexe crée donc un transfert interne : les assurés dont le coût actuariel individuel est plus faible paient plus que leur coût propre, tandis que les assurés dont le coût actuariel est plus élevé paient moins que leur coût propre. Dans ce portefeuille, la prime 60/40 est plus adaptée que la série `total` si l'objectif est de refléter exactement la composition des assurés.

10. Conclusion et synthèse des risques

Le projet montre que la VAP d'une rente dépend simultanément de la mortalité projetée, du taux d'actualisation, du montant de rente et de la composition du portefeuille. L'analyse de sensibilité confirme que le taux d'actualisation est un paramètre majeur : plus le taux augmente, plus la VAP diminue.

La comparaison des modèles StMoMo montre qu'il ne faut pas utiliser Lee-Carter automatiquement. Lee-Carter reste une bonne référence simple, APC devient pertinent si l'effet de cohorte est significatif, et CBD est particulièrement naturel pour les âges élevés et les rentes. Le choix final doit être motivé par la performance hors échantillon, la stabilité des projections et l'interprétabilité actuarielle.

Enfin, la composition femmes/hommes modifie directement la prime unisexe. Une tarification avec la série `total` HMD est simple, mais elle peut transférer du risque si le portefeuille réel est différent de la population globale. Pour ce portefeuille 60/40, la moyenne pondérée des VAP genrées représente mieux l'exposition réelle.
